

# Proxy Design Pattern (scaffold)

This module is a **placeholder** — the pattern is not implemented here yet. The full, runnable, production-mirrored example lives in `Design-Pattern-RealUseCase/RealUseCase_Structural/RealUseCase_Proxy_Design_Pattern`.

## Target UML (what the implementation should look like)

```
<<interface>> Service
| +fetch(id) |
^             ^
|             |
RealService  Proxy
^             | -delegate : Service
+-----+ -cache / guard / lazy-init
client talks to Proxy; Proxy controls access to RealService
```

## Current code, line by line

```
package com.design.patterns.proxy;

public class ProxyDesignPattern {

    public static void main(String[] args) {
        System.out.println("Proxy Design Pattern");
    }
}
```

- `package com.design.patterns.proxy;` — the pattern's dedicated package, ready for the real classes.
- `public class ProxyDesignPattern` — the module's entry class, named after the pattern.
- `public static void main(String[] args)` — standard JVM entry point so the scaffold runs standalone.
- `System.out.println("Proxy Design Pattern");` — prints the pattern name, proving the module builds and runs; replace with a real demo when implementing.
